What is a diesel generator air intake & exhaust system?

The diesel generator air intake and exhaust system (DGAIES) provides the diesel engine with combustion air from the outside. The combustion air passes through a filter and silencer before being compressed by a turbocharger and cooled by the coolant system before entering the individual cylinders for combustion.

Why do generators need air ventilation?

Air Cleanliness: Ventilation helps to remove harmful fumes and foul odors from any enclosed spaces. Generator rooms tend to be in need of air purging as buildup of engine exhaust and other output can be dangerous. Air ventilation systems can also play a role in generator noise reduction.

Why do generators need airflow?

Engines require air to create combustion in the cylinders, so proper airflow is mandatory for the success of generators. Aim for either an upward flow of air around engines or flow from the back of the engine to the front for optimum efficiency. **Air Cleanliness:** Ventilation helps to remove harmful fumes and foul odors from any enclosed spaces.

How should a generator be ventilated?

Preferably, the source of ventilation air should be as low as possible and the air should flow over the entire generator set, thereby cooling the alternator, engine block, and radiator (for sets with unit-mounted radiators) to remove the after-cooler and jacket-water heat.

Where should exhaust air be sourced for a generator?

For generators with remote radiators, it is recommended that the exhaust air should be sourced as high as possible and directly above the generator sets. Significant bypass of ventilation airflow directly into the discharge airflow will lead to reduction in cooling effectiveness and elevated temperatures within the room.

Do generator rooms need air purging?

Generator rooms tend to be in need of air purging as buildup of engine exhaust and other output can be dangerous. Air ventilation systems can also play a role in generator noise reduction. By installing insulated air ducts and using smart layout in regards to where air inlet and outlet locations are, noise levels can be controlled.

The operation between two fuel injections is called a duty cycle. In a four-stroke diesel engine, this cycle is completed by four distinct strokes of the piston, namely intake, compression, expansion and exhaust. If we ...

These engines don't require throttling device to control the intake of air. It takes the same amount of air intake during each suction stroke. While the speed and torque are controlled by ...

The air should flow over the entire generator horizontally, thereby cooling the alternator and effectively purging internal heat. As for the exhaust fans, they should be placed high and directly above the generator to ...

The ductwork design should prevent any recirculation of exhaust air back to the generator area, as this could lead to performance issues. When extending exhaust ductwork, it's important to minimize the number of bends to ...

locate the exhaust pipe outlet (preferably with the generator sets sited to the uppermost floor) at the building roof rather than at low level or the podium. Should it be not viable, it is essential to ...

In order to solve these noise problems, muffler was born. In this article, let's talk about the muffler in the diesel generator set in detail. 1. Introduction to muffler of diesel generator set. Silencer refers to the equipment ...

The general principle of spark-ignited wide open throttle exhaust gas recirculation (WOT-EGR) operation is to return cooled exhaust gases to the cylinder at moderate to high loads, reducing ...

Today, we will briefly introduce the four-stroke diesel working principle analysis of the silent diesel generator. Quiet diesel generator intake stroke: during the intake stroke, the ...

The noise reduction of diesel generator sets needs to deal with the causes of the above noise respectively. The main methods are as follows. 1. Air intake and exhaust noise reduction: the intake and exhaust air channels in ...

They work on the principle of electromagnetic induction, where a conductor moving through a magnetic field generates an electric current. ... This unburned fuel can ignite in the hot exhaust system and cause a dangerous ...
