Kernel-Power Event ID 41 does indicate that the system restarted without shutting down completely. You have taken many effective steps to troubleshoot the problem. Regarding your issue, the old WIFI driver may indeed cause system instability, but we ...

Kernel Power 41 or Event ID: 41 happens when your PC shuts down unexpectedly. This scenario usually indicates a problem with the hardware, but it is not limited to that. To troubleshoot your issue with unexpected shut downs, kindly check these things: Disable overclocking to see whether the issue occurs when the system is run at the correct speed.

This was an annoying issue, but disabling C-state for my AMD cpu in bios fixed it. Seems like when cpu was idling and then needed power back again (often in games or just quitting out of the game after couple of minutes) this caused my pc to freeze and auto restart.

Based on the information you have provided, the problem you are experiencing with "Event 41, Kernel Power" is usually related to system instability or hardware failure. This issue may cause the computer to restart unexpectedly while performing certain tasks. To help you resolve this issue, I suggest you try the following steps:

I built my PC about 2.5 months ago. In the past 2 months I have had a consistent issue where my PC will turn off and automatically turn back on while playing games and I get the Kernel Power event ID 41 Task category (63). This issue is ...

Now click on the blue link, "change advanced power settings". Find "hard disk" in the menu and turn it off by typing in "0" into the box. Make sure to hit apply! Now find "sleep" in the menu and also turn it off by typing in "0". Make ...

what power plan are you running in settings/system/power, click on the Additional power settings link under related settings? Are you on high performance? i see lots of pc that can cope with running full speed but crash at idle, it seems odd to me. you might want to run HWINFO and log system performance to see if any sensors offer a clue.

kernel power errors can be caused by a lot of things. basically it's just when the PC just shuts off and windows doesn't know why. if it just randomly happens fairly often, can you try unplugging the GPU and just using the integrated graphics for a while? couldn't hurt to try reinstalling graphics drivers for the 3080 (uninstall with DDU ...

PSU has a watt display and system typically draws between 550W and 800W in average). Logs: - System - Provider [Name] Microsoft-Windows-Kernel-Power [Guid] {331c3b3a-2005-44c2-ac5e-77220c37d6b4} EventID 41 Version 9 Level 1 Task 63 Opcode 0 Keywords 0x8000400000000002 ...
